Rooted in Trust is a global and local humanitarian response by Internews that aims to combat the spread of rumors and misinformation around COVID-19 in Lebanon. Internews, in collaboration with Maharat Foundation, are collecting rumors through social media monitoring in an effort to combat misinformation and to provide vulnerable communities with accurate information.

Internews and Maharat collected and analyzed 433 rumors about COVID-19 circulating on social media between January 5, 2021 and January 31, 2021. This bulletin highlights community perceptions and criticisms about the following topics:

- Home remedies for preventing COVID-19.
- Re-infection of COVID-19.
- Testing and false negatives
- A false claim that the COVID-19 vaccine and the PCR test could cause genetic modifications in people.

COVID-19 SITUATION IN LEBANON

According to the World Health Organization (WHO), to date there have been 324,859 positive cases of COVID-19 with 3,737 deaths in Lebanon as of February 10, 2021. Due to the increase of positive cases, the nation-wide lockdown that began on January 14, was extended until February 22. (1) The Ministry of Public Health (MoPH) presented the national vaccine framework on January 27, 2021, and launched an online platform for COVID-19 vaccination registration. Their call centre will support people who face difficulties accessing the platform, however the calls will not be free of charge. The vaccines are expected to reach Lebanon around mid-February, and all eligible populations should be covered by the end of 2021.

WHAT IS A RUMOUR

Rumors are information collected from a first-hand source within the community which could take the shape of a question, criticism, or general comment about a situation or topic. In this bulletin, rumors were collected as data points pulled from social media pages by Internews and Maharat from January 5 to January 31, 2021 across various platforms such as Facebook, Twitter, Instagram and WhatsApp.
Since the beginning of the COVID-19 pandemic, rumors have been circulating on social media about home remedies to prevent or treat COVID-19. Although drinking pomegranate juice or eating bananas have many health benefits and are great sources of vitamins and essential nutrients, they do not prevent COVID-19.

It is important to note that The University of Queensland dismissed the claim as false, and discouraged people from sharing the video.

To date, the best way to prevent the spread of the virus is through social distancing, washing hands, and wearing masks. According to the World Health Organization (WHO), there are no foods or drinks known until now that prevent COVID-19.

According to the WHO, there is no long-term immunity for COVID-19 after contracting it. Although they are rare, some countries have reported cases of reinfection, and studies are ongoing to better understand patient immunity following an infection.

Recent studies do point to short-term periods of immunity for recovered COVID-19 patients, however the exact length of time for immunity remains unknown and varies from person to person. A recovered COVID-19 patient is still advised to wear masks and practice social distancing to avoid reinfection or further spread of the virus.

Studies suggest it takes about 10 days to start making antibodies that can target the virus for the patient to develop a strong immune response. If the adaptive immune response is powerful enough, it could have a lasting memory of the infection that will give protection in the future. However, a recent study shows most people who have had the virus are protected from catching it again for at least 3 months. Some are reinfected, and even if asymptomatic can still accommodate high levels of the virus in their noses and mouths, which can be passed on to others. There is still a lot to learn about COVID-19, so it is important to continue practicing protective measures to safeguard our community and those around us.
In a new study, Johns Hopkins University researchers found that testing people for SARS-CoV-2 (the virus that causes COVID-19) too early in the course of infection is likely to result in a false negative test, even though they may eventually test positive for the virus. If someone tests negative early on in their infection, they risk further transferring the virus before their symptoms are evident. After a negative test result, a person should continue to isolate and distance from relatives and friends. If symptoms persist, they should get retested.

Moreover, due to the high price of the PCR test, many people have been resorting to makeshift home tests, believing they are effective. To date, the only way to test for infection is through a Rapid Diagnostic test or the PCR test, which is most accurate 5-7 days after being exposed to an infected person, or immediately when symptoms start to appear. The Rapid Diagnostic test has a lower detection rate for COVID-19 but is useful in detecting community spread and contact tracing. For individual, suspected cases of COVID-19, the PCR test is recommended.

"The negative PCR tests from the past few days might in fact be positive, meaning that people who were tested are infected by COVID-19, and this has led to the massive spread of the virus recently."

Farewell to PCR testing. There is an effective way to find out whether you are infected with the COVID-19 virus or not. Place a banana peel in your mouth for one minute, if the color of the peel turns light brown, the person is infected. Banana peels have substances that react to COVID-19.

Social media platforms (like Facebook, Twitter, and WhatsApp) allow anyone to publish their thoughts or share their stories to the world. This has led to a flood of fake news and the spread of rumors and misinformation, which is why we should always take into consideration the below. When you come across news or new information on social media:

1. Identify the news outlet
2. Check if other news outlets are reporting on the same story
3. Double check if the WHO or MOPH have corroborated the information
4. Compare the information presented across different sources to ensure the story is based on scientific facts
5. Don’t rely solely on Facebook groups, Twitter accounts or WhatsApp groups for news on COVID-19. Instead, make sure any news you hear on social media is confirmed by trusted sources such as the WHO
6. Keep in mind that videos and photos can be manipulated
7. Check the date and origin of the story to confirm whether this information is recent and still valid.
